ALLOMETRIC BIOMASS EQUATIONS FOR 98 SPECIES OF HERBS, SHRUBS, AND SMALL TREES

LIBRARY
Forest Service - US Dept. of Agriculture
1992 Folwell Avenue St. Paul, Minnesota 55108

W. Brad Smith, Mensurationalist
and Gary J. Brand, Associate Mensurationalist

ABSTRACT.—Biomass regression coefficients from the literature for the allometric equation form are presented for 98 species of shrubs and herbs in the northern U.S. and Canada. The equation and coefficients provide estimates of grams of biomass (ovendry weight) for foliage, woody stem and total biomass.

KEY WORDS: Regression, metric, dry weight, herbs, shrubs.

Biomass estimates for herbs and shrubs have many uses in determining wildlife habitat and forest fuel conditions. Although many independent variables and equations have been chosen in biomass studies, the simple allometric equation is most frequently used (Stanek and State 1978, Hitchcock and McDonnell 1979). This equation for predicting biomass in grams (Y) from stem diameter or percent cover (X) has two forms:

$$Y = aX^b \quad (1)$$

or

$$\ln Y = a + b \ln X, \quad (2).$$

The purpose of this paper is to compile coefficients for these equations for species in eastern Canada and the northern United States from seven sources (Telfer 1969, Grigal and Ohmann 1977, Ohmann *et al.* 1976, Brown 1976, Roussopoulos and Loomis 1979, Ohmann *et al.* 1981, Connolly 1981).

For convenience, Eq. 2 may be put in the form of Eq. 1 by solving for Y and transforming the coefficients. The new equation becomes:

$$Y = a' X^b \quad (3)$$

where $a' = e^a$ and coefficients a and b are the same as in Eq. 2. The equation coefficients from Ohmann *et al.* (1976), Grigal and Ohmann (1977), Roussopoulos and Loomis (1979), Ohmann *et al.* (1981), and Connolly (1981) are taken directly from the original sources. Telfer (1969) and Brown (1976) reported coefficients for the logarithmic form, which we converted. Telfer's coefficients were additionally adjusted to convert the independent variable from basal diameter in mm to cm. Thus, for Telfer $a' = e^a 10^b$ in Eq. 3.

Roussopoulos and Loomis fit their data to Eq. 2 but converted these coefficients after correcting for the bias inherent in the fitting of the logarithmic form (Baskerville 1972, Yandle and Wiant 1981). Brown indicated that the effects of this bias on his biomass estimates ranged from 2 to 9 percent with an average of 5 percent. The coefficients presented by Brown are unadjusted for bias, as are those presented by Telfer. All coefficients presented are for estimating biomass in grams ovendry weight.

One caution is necessary: some of the equations use stem diameter at 15 cm as the independent variable and others use basal diameter. Roussopoulos and Loomis (1979) present a regression technique for estimating basal diameter at 15 cm, thereby facilitating the use of basal diameter equations even though field measurements may have been collected at 15 cm.

Refer to the original publications for details about methods, specific locations of data sources, or any other questions regarding the biomass studies.

^{1/} G18 = total aboveground biomass per 1,800 cm² (ovendry weight).

^{2/} PC = ground cover in percent.

^{3/} Source for coefficients is Ohmann et al. (1981). Data collected in northern Minnesota.
