

A scanning electron micrograph (SEM) showing a dense array of plant cells. The cells are roughly rectangular and arranged in a brick-like pattern. Several stomata are visible, which are small openings between cells, each surrounded by two guard cells. The overall color is a vibrant green, typical of plant tissue.

# Plants and the terrestrial surface energy balance

**Or: Why you should take AOS520**

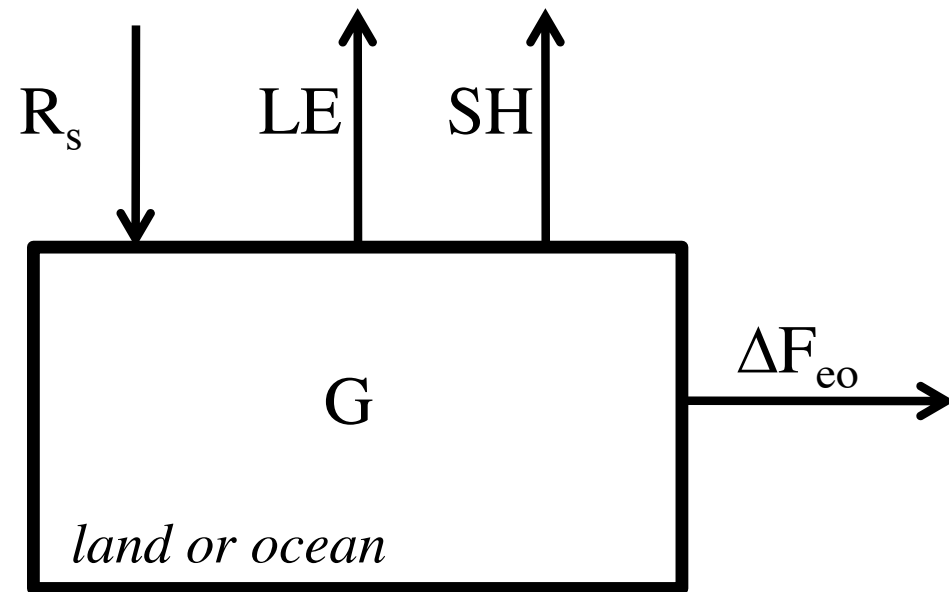

**Ankur R Desai**

# Energy Balance of the Surface

- Apply first law of thermo to the surface (as opposed to atmosphere)
- $G = \text{Storage} = d(\text{Surface Energy})/dt = dE_s/dt$
- $R_N = \text{Net Radiation}$   
= SW-LW
- LE = Latent
- SH = Sensible
- $\Delta F_{eo} = \text{Transport}$

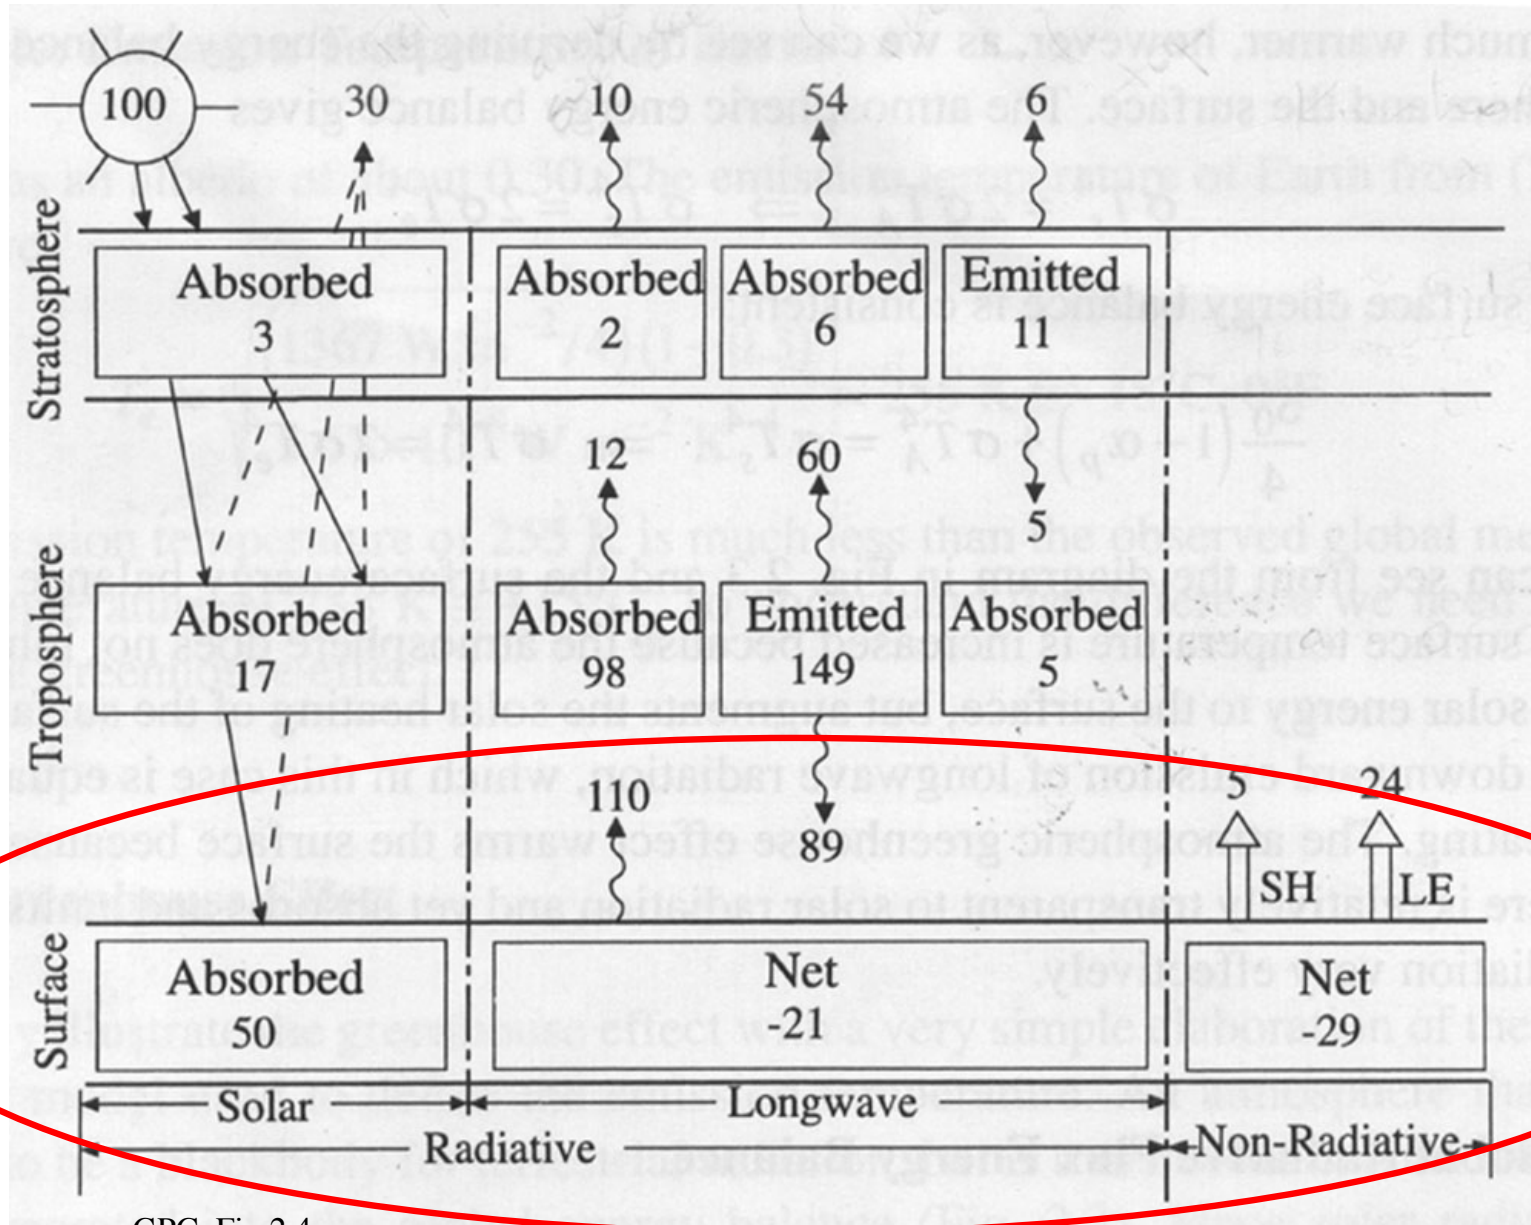

## BALANCE EQUATION

$$G = R_N - LE - SH - \Delta F_{eo}$$

# Global Energy Flow

$$100 = 342 \text{ W/m}^2$$

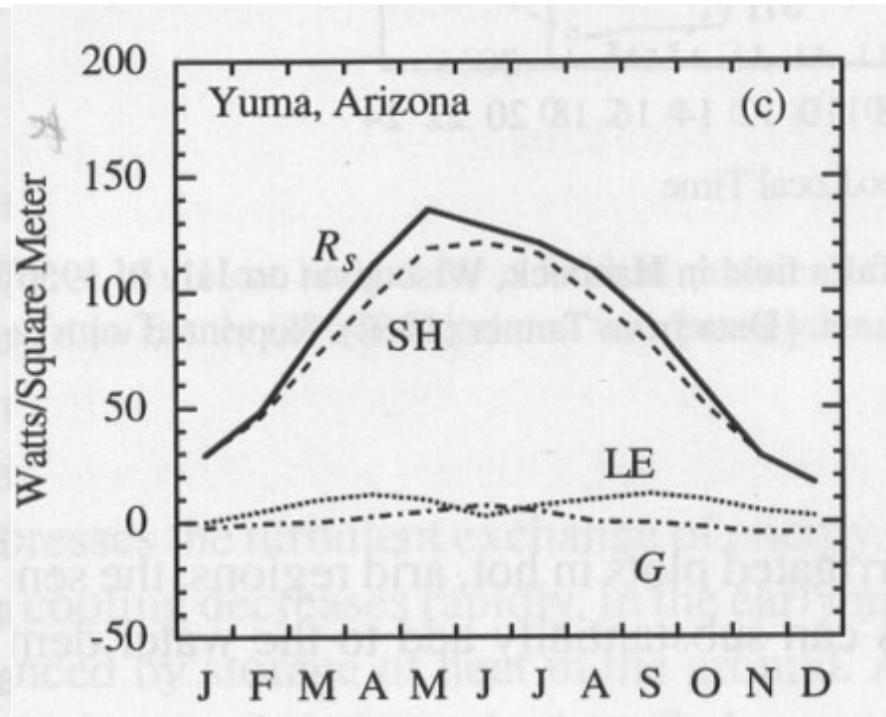

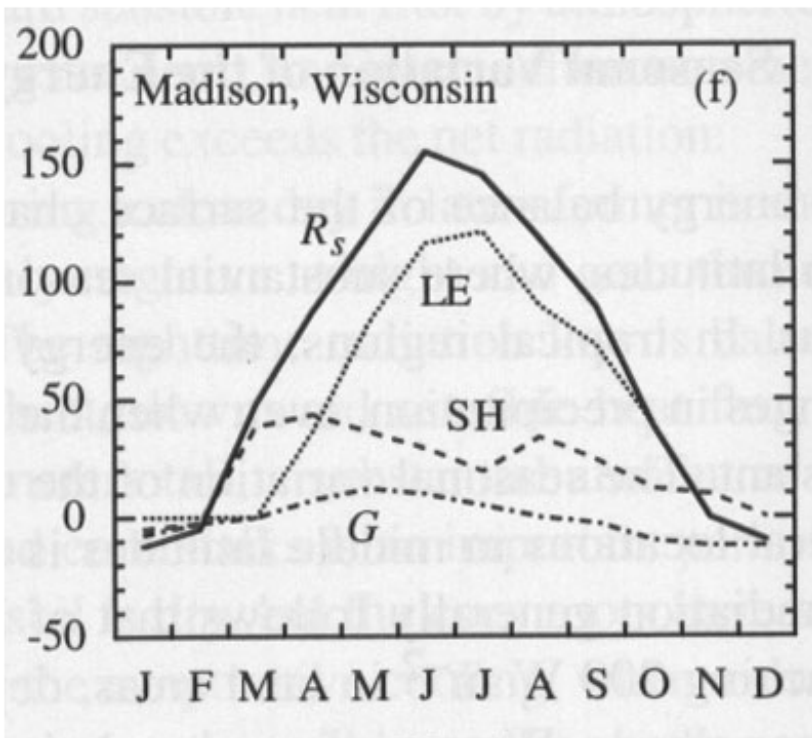

GPC, Fig 2.4

# Hydrology: Global

# Seasonal: Madison vs. Arizona desert

$$G = R_N - LE - SH - \Delta F_{eo}$$

# Hydrology: Terrestrial

# Hydrology: Canopy

# Major points

- Terrestrial evapotranspiration (ET, aka latent heat flux) is dominated by transpiration (T)
- T is biologically regulated, function of species specific adaptations to climate, soils, competition
- Stomata regulate input of CO<sub>2</sub> and release of H<sub>2</sub>O, plants limit cavitation in xylem while maximizing growth/reproduction
- As a result, biological primary productivity and T are tightly linked, can be tracked by water use efficiency (WUE)
- Any changes to plant biogeochemistry (such as CO<sub>2</sub> fertilization) influence plant water loss, but is also regulated by atmospheric demand (VPD), soil moisture, plant acclimation
- Regional and global surface energy balance influenced by these processes, leading to net changes in sensible and latent heating of atmosphere, albedo, and hence local and regional meteorology
- Take AOS 520: Bioclimatology to learn more!
